Title

SEARCHING AND INTEGRATING QUERY  
INTERFACES USING DOMAIN ONTOLOGY

**Abstract:**

In addition to billions of Web pages indexed by search engines, the Web also contains a large number of databases whose contents is 500 times larger than Surface Web and are only accessible through query interfaces. This type of web is known as Hidden Web. Its content is out of reach of traditional search engines and its growth is increasing at extraordinary rate. To search the hidden web data, one has to fill these HTML forms manually. That's why Search query interfaces are considered as entrance to Hidden web databases. So, to explore the Hidden Web, we must explore its entrance first. Many different integration solutions have been proposed so far. This paper proposes a technique to detect and construct an integrated query interface that integrates a set of web interfaces over a given domain of interest. This interface is used to fire the queries over various search interfaces of hidden web sites. The proposed strategy does that by focusing the crawl on a given topic i.e by wisely looking at domain ontology which leads to pages that contain domain specific search forms.

**Keywords:** *Hidden web (deep web), search query interface, Hidden web crawler, Domain Ontology.*

**INTRODUCTION:**

Search query interfaces act as entry points to the Hidden web which contains substantial amount of high quality structured data. This data is out of reach of traditional search engines. The traditional search engines use inverted index as a data structure to index the web data and keyword interface to retrieve the data. But, surfacing the Hidden Web is more difficult task in many respects. First, the index structures for the hidden web deal with the structured data as well as the large volume of data. Second, the Search query interfaces often have more than one attribute and require their respective values to be submitted. For data sources with multi-attribute interfaces, multiple attributes and their respective values should be stored and the resulting HTML pages should be added into a deep web search engine index.

For instance, suppose a user wants to search some information (say price of a used car) hidden behind a search interface on a site. The user needs to follow the following steps.

1. He/ She has to discover the URLs of the used car sites.
2. Visits homepages of all this kind of web sites.
3. Send queries through HTML forms.
4. Extract the relevant information from the result web pages.
5. Compare or integrate the results from multiple sources.

Two examples of search query interfaces are shown in figure 1. User has to fill the fields of these types of forms and then he/she will get the result pages.

The figure displays two search interfaces. The left interface, titled 'Search Used Cars / Second Hand Cars', features a navigation bar with options like 'Buy Used Car', 'Sell Your Car', and 'Used Car Valuation'. It includes a search bar with 'Search by Profile ID' and a 'Go' button. Below are dropdown menus for 'Make', 'Model', 'Budget (Rs.)', 'City', and 'Show', along with a 'Search' button. The right interface, titled 'Buy Used Cars & Bikes', has tabs for 'Cars' and 'Bikes'. It contains dropdown menus for 'Select Make', 'Select Model', and 'Select City', an 'Advance Search' link, and a 'Search' button.

**Fig 1: Search interface Examples**

Therefore, there arises the need for new information services that can help users to find the information in integrated form. To minimize user effort, the problem of automatically interaction with information sources in the Hidden web is explored in this paper.

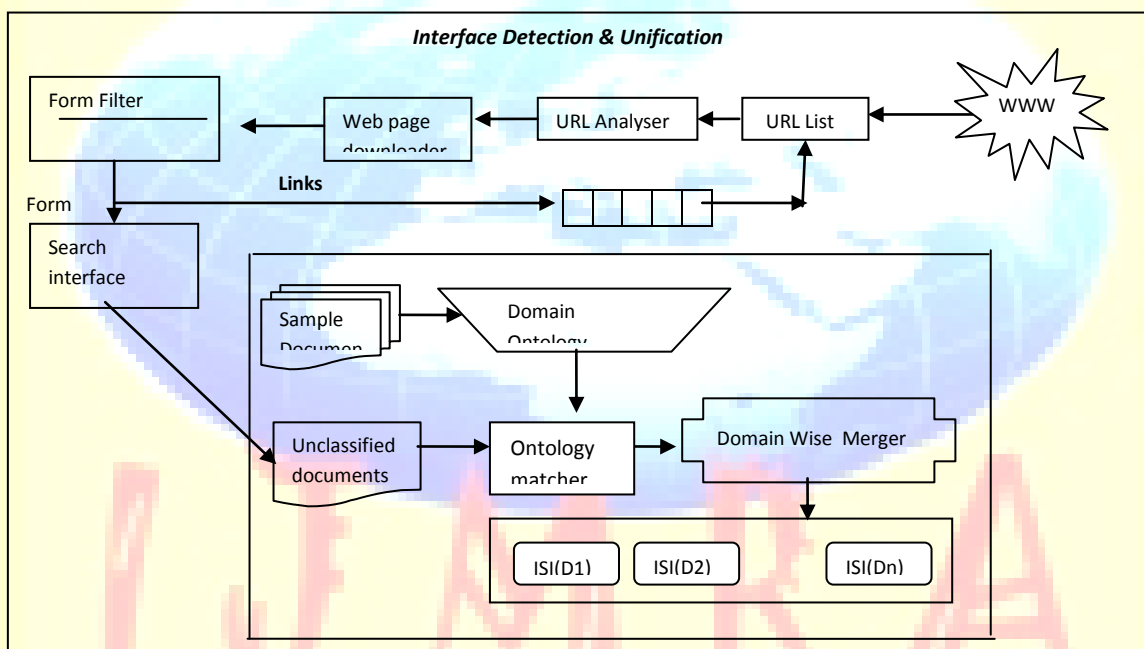

The paper has been organized as follows: Section 2 describes the proposed work that detects and extracts the search query interfaces, by looking at domain word, attributes and their synonyms in the source code of the web page. If these are present then this means this interface is search interface of our interest. The section also compares the efficiency of proposed method with the previous one [1]. Section 3 constructs an unified search interface by accumulating query interfaces to the Base interface. Section 4 draws the conclusion and describes the future research.

**Proposed work:**

A search query interface allows a user to search some set of items without altering them. The user enters a query, by typing or selecting options, to describe the items of interest. Results might be a page linking to items, a page containing items or a single page. The items found should match the query. The majority of search interfaces on the Web are HTML forms. Therefore the problem is: given a URL List, find all HTML search interfaces (search forms).

This proposed architecture automatically detects the domain specific search interfaces by looking the domain ontology for particular domain in the source code of web page. The framework is shown below in figure 2.

**Fig 2: Interface Detection and Unification Architecture**

**Building Domain Ontology:**

Domain ontology can be defined as information architecture in a specific domain [10]. It provides a structured way of describing knowledge. It also defines the concepts about Web page categories and their hierarchical relationships. Ontology is a specification of conceptualization that is description of concepts and their relationships[10]. Ontology is composed of concepts,

attributes and the relation among concepts. Concept is anything that can be described. It can be a real, assumed, concrete or abstract. A concept in ontology can be described by the attribute values. The main function of ontology is to provide the knowledge base needed for the classification of search results [6]. Organizing search results into hierarchical structure can help users navigate, seek and find more quickly information they are looking for.

Since Hidden Web is a huge repository for all domains, we confined our research to car domain. To build the ontology in this domain, used car keyword is pushed into the search box of Google and result index is extracted as shown in figure 3.

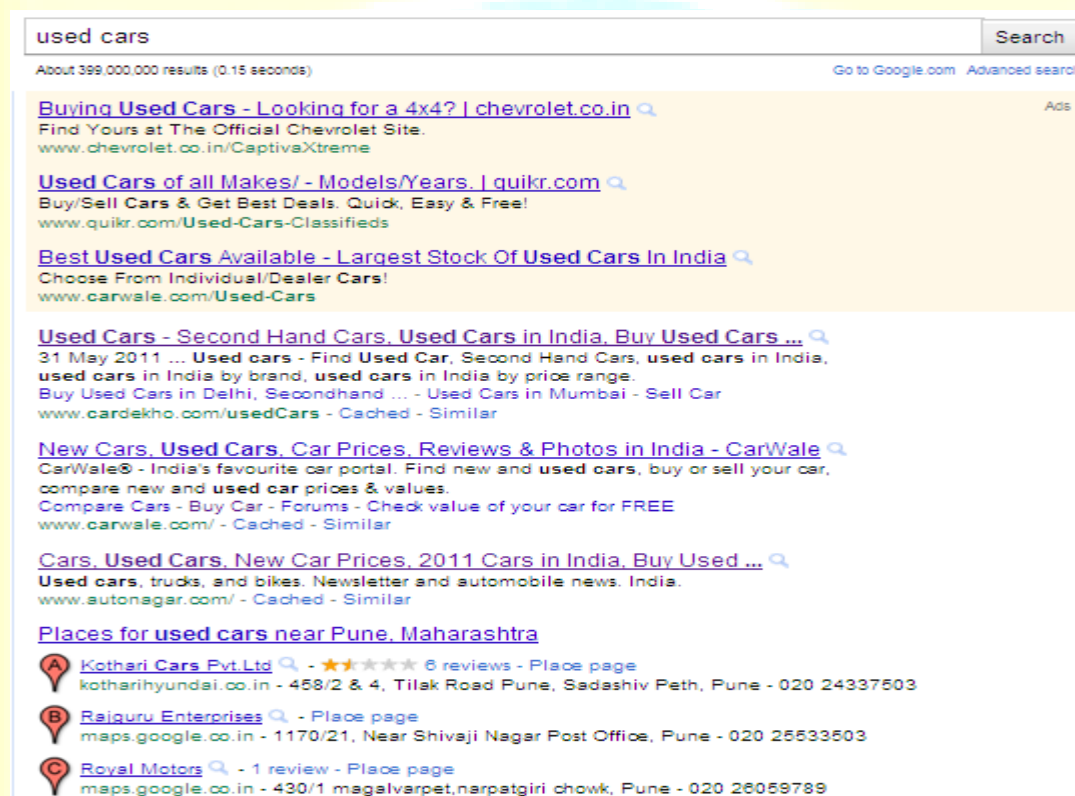

Fig 3 Google results for used cars

### Attribute Extraction:

Out of large set of results, 4 sites are taken randomly as sample documents. These sites are downloaded to extract the search attributes. Algorithm for extracting the attributes is given below in figure 4.

Fig 4 : Algorithm for

```

Algorithm1 attr_extract(URL List)

1. Alist= $\phi$  and i=0;

2. Pick URL one by one from URL List

2. x=document.getElementsByTagName("select");

// reach upto the point where select is present.
    
```

A

### Attribute Extraction

This algorithm works by taking the URL one by one from the list. Because all the attributes of search form are preceded by tag <select>, attributes can be extracted by extracting the text value (innerHTML) followed by that tag. The output of this phase is given in table 1.

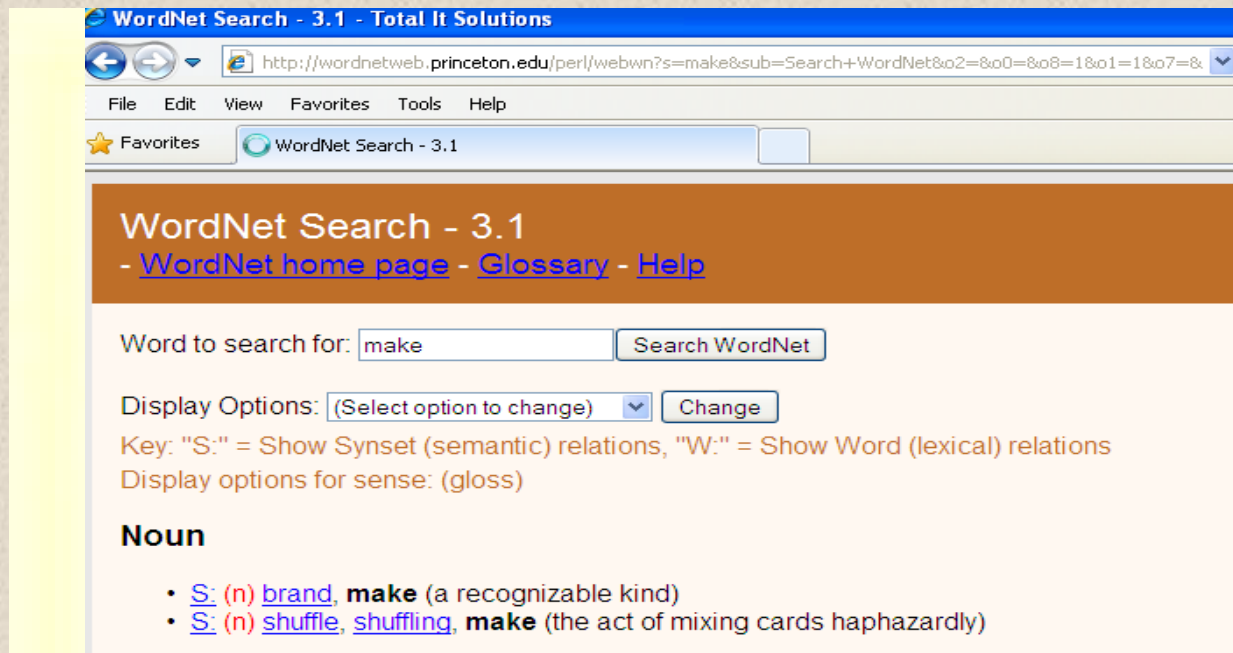

Table 1 Extracted Attribute list

Website	Attribute list
www.autonagar.com	make, model, city
<a href="http://www.carwale.com">www.carwale.com</a>	make, model, city, price
<a href="http://www.gaadi.com">www.gaadi.com</a>	Make, model, budget, city
<a href="http://www.cartradeindia.com">www.cartradeindia.com</a>	Brand, model, state, city

### Interface Detection and Extraction:

To detect and extract search query interfaces, an algorithm haven below in figure 5 has been proposed which looks for the synonyms of domain word and also the synonyms of attributes of sample form. To find the synonyms, wordnet (online dictionary) is used[12].

**WordNet** is a lexical database for the English language. It groups English words into sets of synonyms called *synsets*, provides short, general definitions, and records the various semantic relations between these synonym sets[12]. To make the ontology, we have used this dictionary and synonyms are extracted and a list is made for each attribute. Synonyms for make are shown in figure 5.

**Fig 5 synonym list for make from wordnet**

For make, the synonyms are (brand, shuffle). Similarly for model, synonyms are (framework, example, role model, poser etc.), for price list is (Price, monetary value, cost) and for city (metropolis, urban centre) is the list.

### **Ontology Table:**

To make the domain ontology repository, synonyms from the wordnet dictionary are collected along with the attributes from all 4 sites and are stored in database as shown in Table 4.2.

Table 2 Ontology table

Attribute(ai)	Synlist
Make	Select make, brand
Model	Model, framework, example, poser
City	City, cities, metropolis
Price	Price, range, budget

Algorithm for Interface detection is given below in figure 6.

#### Algorithm Interf\_detect2(URL List)

1. Pick one by one URL from URL list
2. Check for the string login or registration or signup in URL  
If (present) Then “ it is a login/ registration form”; discard URL and Go to step 1 .  
Else Goto step3.
3. Download the source code and save.
4. check the source code for tag <form> and </form> // Form analyses  
if (present) Goto step 5  
Else “ It is a simple web page”. Goto step 1.
5. check source code // Search interface analysis  
if ( input-type=”login” or “registration” or” sign up”)or (having password control )  
then Goto step 1.  
Else Goto step 6.
6. if the htmlsrc.Contains(“make”)|| htmlsrc.Contains(“brand”) &&  
htmlsrc.Contains(“model”)||htmlsrc.Contains(“framework”)||htmlsrc.Contains(“example”)  
||htmlsrc.Contains(“models”) && htmlsrc.Contains(“city”) || htmlsrc.Contains(“cities”) &&  
htmlsrc.Contains(“search”) && htmlsrc.Contains(“price”) || htmlsrc.Contains(“cost”) ||  
htmlsrc.Contains(“budget”) || htmlsrc.Contains(“range”) && htmlsrc.Contains(“car”))||  
htmlsrc.Contains(“used car”) || htmlsrc.Contains(“submit”) ||htmlsrc.Contains(“search”)  
then Goto step 7.  
Else Goto step 1.
7. Make a list of URLs i.e the list of web search interfaces

**Efficiency of proposed algorithms:**

There are two widely used metrics for evaluating the correctness or accuracy of algorithms. These are Precision and recall. There are four ways of being right or wrong:

1. TN / True Negative: case was negative and predicted negative
2. TP / True Positive: case was positive and predicted positive
3. FN / False Negative: case was positive but predicted negative
4. FP / False Positive: case was negative but predicted positive

Precision is defined as fraction of retrieved documents that are relevant to the search. High **precision** means that everything returned was a relevant result.

$$\text{Precision} = \frac{tp}{tp + fp}$$

Recall is defined as fraction of documents that are relevant to the query that are successfully retrieved. In even simpler terms, a high **recall** means you haven't missed anything.

$$\text{Recall} = \frac{tp}{tp + fn}$$

**Accuracy:**

$$\text{Accuracy} = \frac{tp + tn}{tp + tn + fp + fn}$$

Table 3 summarizes the efficiencies of the first method that is proposed earlier [1] and the proposed method.

**Table 3: results for two algorithms**

Algo	tn	Tp	Fn	fp	Precision	Recall	Accuracy
1.	9	10	1	2	83%	90%	86
2.	12	10	0	0	100%	100%	100%

**Unification of Interfaces:**

Structured websites tend to publish different product features and properties. For example product car has following properties (make, model, city, year, price). Website w1 want to give (make, model, city, year, price) fields in the search form, website w2 may select make, model, city only. There would not be problem with user, but problem is for someone who collects and compiles this information.

There is no proper solution for this. We can take the union of two attribute list like (make, model, city, year, price)  $\cup$  (make, model, city) = (make, model, city, year, price).

For the experimentation purpose, we have chosen 4 sites and the attributes are:

**Table 4 Attribute list from different websites**

Website	Attribute list
www.autonagar.com	make, model, city
<a href="http://www.carwale.com">www.carwale.com</a>	make, model, city, price
<a href="http://www.gaadi.com">www.gaadi.com</a>	Make, model, budget, city
<a href="http://www.cartradeindia.com">www.cartradeindia.com</a>	Brand, model, state, city

**Unified list of attributes:**

(make, model, city)  $\cup$  ( make, model, city, price)  $\cup$  (Make, model, budget, city)  $\cup$  ( Brand, model, state, city) = (make, model, city). After getting the unified list of attributes, ontology table i.e table 2 is again modified as shown in Table 5.

**Table 5: Ontology table2**

Attribute(ai)	Synlist
Make	Select make, brand
Model	Model, framework, example, poser
City	City, cities, metropolis
Price	Cost, range
Year	yr

An algorithm for the method of interface unification is given below in figure 7.

### **Algorithm for Unification of Interfaces:**

#### **Algorithm Unif\_interf (URL List)**

1. For each URL in URL List  $U_1, U_2, \dots, U_n$
2.  $NAlist = attr\_extract(U_i)$ ;
3. For each attribute from  $NAlist$   $na_1, na_2, \dots, na(i), na(n)$  repeat step 4.
4. if  $na(i) = a(i)$  in Table 4.2  
then rename  $na(i)$  with  $a(i)$  and GOTO step 5.  
else exit;
5. Display the list of attributes and form a new search query form.

This algorithm works by taking URL one by one and extracting the attributes from all websites. If the attribute from particular website matches with the attributes from the ontology table 2 then the unified interface will have the attribute with the same name as in ontology table and if the attribute is not present then it will be added to attribute list.

### **Experiments and results:**

For experimental purpose, we have taken 22 sites of used car domain and made a crawler in C#. This crawler returns “valid” message if the site contains search interface and displays “invalid” message it does not. Results are shown in figure 8 and it shows 100 % results.

**Fig 8: Results of Proposed system**

### **Conclusion:**

This paper automatically detects the domain specific search interfaces by looking the domain word, its synonyms, attributes from sample documents and its synonyms from wordnet in the source code of webpage. The problem of integrating large-scale collections of query interfaces of the same domain has been designed and developed by transforming a set of interfaces in the same domain of interest into a global interface. This interface will permit the crawler to fire the

queries to interfaces of target sites and it also provides users to access information uniformly from multiple sources of a given domain.
